Depths to Selected Stratigraphic Horizons in Oil and Gas Wells for Upper Cretaceous and Lower Tertiary Strata of the Uinta Basin, Utah

By Ronald C. Johnson and Laura N.R. Roberts

Introduction

Depths to selected stratigraphic horizons for Upper Cretaceous and lower Tertiary strata in the Utah portion of the Uinta Basin are presented here for 745 wells (fig. 1, table 1). The name of each well, along with a section, township, and range location, API number, and kelly bushing elevation are included in the table. The Upper Cretaceous and lower Tertiary stratigraphy of the Uinta Basin of Utah is complicated by stratigraphic nomenclature that is inconsistently applied as well as by the use of many stratigraphic names that are used only locally within the basin. The purpose of this study is to help clarify these inconsistencies and provide a database for use in the Uinta-Piceance oil and gas assessment.

Table 1 includes subsurface depth determinations to nine stratigraphic horizons (fig. 2) in ascending order: (1) top of the Upper Cretaceous Castlegate Sandstone or lower tongue of the Castlegate Sandstone; (2) top of the Upper Cretaceous Sego Sandstone; (3) top of the Upper Cretaceous Bluecastle Tongue of the Castlegate Sandstone; (4) top of the Upper Cretaceous Mesaverde Group; (5) base of a persistent ostracodal limestone zone in the Eocene Green River Formation; (6) base of the Long Point Bed of the Green River Formation; (7) top of the carbonate marker, an informal marker in the Green River Formation; (8) base of the R-4 rich oil-shale zone of the Parachute Creek Member of the Green River Formation; and (9) top of the Mahogany oil-shale bed of the Parachute Creek Member of the Green River Formation. These units were chosen because they occur over a significant part of the basin and, therefore, the maps derived from these data show regional structure and thickness trends. Structure contour and isopach maps generated from data in the table, along with some interpretations of the geologic history of the basin based on these maps, are also presented.

Upper Cretaceous Units

The Upper Cretaceous Castlegate Sandstone (fig. 2) occurs throughout the Uinta Basin and is easily identified on geophysical logs. Over much of the western part of the basin the Castlegate is subdivided into an upper Bluecastle Tongue and a lower tongue (fig. 2), which are separated by the

Neslen Formation (Fouch and others, 1992). The Bluecastle was deposited in a fluvial braidplain environment (Fouch and others, 1992, fig. 12). The environment of deposition for the main body of the Castlegate Sandstone varies from braidplain in the western part of the basin, to coastal plain in the central part, and to thin shelf sandstone in the eastern part (Fouch and others, 1992). The Bluecastle Tongue was originally considered a bed within the Neslen Member of the Price River Formation (Fisher, 1936) west of the Green River and a member of the Neslen Formation where it occurs locally east of the Green River (Fisher and others, 1960). The Bluecastle Tongue merges with the main body of the Castlegate Sandstone in the westernmost part of the Uinta Basin and beyond the area studied in this report. To the east, the Bluecastle grades into nonmarine coastal plain rocks of the Neslen Formation (Fouch and others, 1992, fig. 12).

The Sego Sandstone is present only in the eastern part of the basin (fig. 2). Here, the lower tongue of the Castlegate Sandstone is separated from the rest of the Mesaverde Group by the Buck Tongue of the Mancos Group. The Sego Sandstone is the basal sandstone in the overlying part of the Mesaverde Group. It was originally mapped in the southeastern part of the Piceance Basin in westernmost Colorado by Erdmann (1934) and in the eastern part of the Uinta Basin by Fisher (1936). The Sego Sandstone was deposited in a variety of marginal-marine settings (Francyzk and others, 1990).

Top of the Upper Cretaceous Mesaverde Group

Of the nine stratigraphic horizons in table 1, the top of the Upper Cretaceous Mesaverde Group (fig. 2) was the most difficult to pick. An unconformity occurs between the Upper Cretaceous Mesaverde Group and the overlying lower Tertiary strata throughout the eastern and central parts of the Uinta Basin. Continuous deposition between Upper Cretaceous rocks and lower Tertiary strata may have occurred in the westernmost part of the Uinta Basin (Fouch and others, 1983) and west of the area considered here. Weathering during the time gap represented by the unconformity kaolinized sandstones in the uppermost part of the underlying Mesaverde

Figure 1. Study area and approximate locations of wells examined in this report. Due to the proprietary nature of exact locations, wells are plotted in the center of the quarter sections in which they were drilled. Location of study area shown on insert map.

Group producing a distinctive white zone that can be recognized in outcrop throughout much of the eastern Uinta Basin east of the San Rafael Swell (fig. 2) (Francyzk and Pitman, 1987). This weathered zone is also present on the Douglas Creek arch, which forms the east margin of the Uinta Basin, and the zone is present in the Piceance Basin to the east (Johnson and May, 1978, 1980). Conglomerates derived mainly from Paleozoic and Mesozoic sedimentary rocks occur above the weathered zone in the eastern Uinta Basin. These conglomerates were first described by Fisher and others (1960) and have been referred to as “beds at Dark Canyon” (Fouch and Cashion, 1979), “conglomerate at Dark Canyon” (Keighin and Fouch, 1981), and “Dark Canyon sequence” (Francyzk and Pitman, 1987). A similar conglomeratic sequence has been described in many areas of the Piceance Basin (Johnson and May, 1980).

The weathered zone and overlying conglomerates can be recognized in the subsurface in the eastern half of the Uinta Basin if good sample descriptions are available. The contact can be difficult to pick using only geophysical logs. In the eastern part of the basin, east of the crest of the San Rafael Swell, the overlying lower Tertiary interval can be very sandy and can resemble the uppermost part of the Mesaverde Group in geophysical logs. It is likely that some sort of paleovalley system was carved into the Mesaverde Group during the long time gap represented by the unconformity. Paleovalleys could be filled with reworked sediments from the underlying Mesaverde Group and difficult to detect in the subsurface. Near the crest of the San Rafael Swell, the Paleocene Flagstaff Limestone occurs unconformably above the Upper Cretaceous Mesaverde Group (Lawton, 1986, fig. 11). In wells in this area, such as the Energy Reserve Group no. 2 Indian Canyon well in sec. 14, T. 6 S., R. 7 W. (no. 14 on fig. 1, table 1), the top of the Mesaverde Group is placed at the first major sandstone below the lowest limestone bed of the Flagstaff. The top of the Mesaverde Group was picked in only one well in the western part of the basin, west of the San Rafael Swell, the Chevron no. 1 Strawberry unit in sec. 10., T. 5 S., R. 11 W. (no. 3 on fig. 1, table 1). In this well the top of the Mesaverde Group is placed at the base of a 340-ft-thick conglomeratic unit.

Lower Tertiary Units

The base of the Eocene Green River Formation is the next highest horizon for which data are recorded in table 1. The base of the Green River Formation occurs at or near the base of a persistent ostracodal limestone zone throughout much of the Uinta Basin (fig. 2). Johnson (1989) traced this zone in the subsurface in an east-west direction across much of the Uinta Basin. Local informal names used for this unit include the Uteland Butte limestone in the Greater Natural Buttes gas field (Osmond, 1992, fig. 7), the basal lacustrine phase of the Green River Formation where it outcrops in Indian Canyon in

the western part of the Uinta Basin (Bradley, 1931, pl. 3), and the Willow Creek interval (Roberts, 1964). These ostracodal limestones were deposited during the maximum extent of the fresh-water stage of Eocene Lake Uinta as described by Johnson (1985). A similar fresh-water stage was present at the same time in the Piceance Basin to the east, and these two lakes may have connected across the Douglas Creek arch (Johnson, 1985). Rocks deposited by this stage in the Piceance Basin are included in the Cow Ridge Member of the Green River Formation (Johnson, 1984). In a relatively restricted area near the basin trough, lacustrine rocks extend downward more than 5,000 ft below the ostracodal zone to near the Cretaceous-Tertiary boundary (fig. 2). Lacustrine deposition may have begun here as early as Late Cretaceous Maastrichtian time (Fouch and others, 1983). For wells in this limited area, the base of the Green River Formation listed in table 1 is still the base of the persistent ostracodal limestone zone rather than that of the lowest lacustrine rocks.

The next stratigraphic horizon for which data are recorded is the base of the Long Point Bed of the Douglas Creek Member of the Eocene Green River Formation (fig. 2). The Long Point Bed was deposited during a major transgression of Eocene Lake Uinta (Johnson, 1984) and is the lowest lacustrine unit that can be traced between the Uinta and Piceance Basins across the intervening Douglas Creek arch (Johnson, 1985). Although the Long Point Bed is time transgressive, the time represented by the transgression is thought to be fairly brief (Johnson, 1985). The bed overlies alluvial rocks throughout much of the Uinta Basin and is easy to identify on geophysical logs provided that sample descriptions are also available for some of the wells. In some areas in the eastern and central parts of the Uinta Basin, where the Long Point Bed directly overlies older lacustrine rocks, the position of the Long Point Bed is marked by a transition from marginal-lacustrine ostracodal limestone and sandstones to offshore lacustrine shale.

The last three horizons for which depth determinations were made, the carbonate marker, the base of the R-4 rich oil-shale zone, and the top of the Mahogany bed, are key lacustrine marker beds that are probably not time transgressive. The carbonate marker as used by Ryder and others (1976) is a carbonate-rich mudstone unit, averaging about 50 ft thick, that was deposited throughout the entire offshore area of Lake Uinta (fig. 2). It was deposited during one of the most expansive stages of Lake Uinta and can be recognized throughout a large area of the basin. The carbonate marker probably represents a period when carbonate was chemically precipitated from the water column and correlates with a similar marker in the Piceance Basin called the orange marker (Johnson, 1985).

The R-4 (rich oil-shale zone) of the Parachute Creek Member of the Green River Formation (fig. 2) is a widespread oil-shale zone that can be traced throughout much of the Uinta and Piceance Basins. It was first recognized by Cashion and Donnell (1972), who demonstrated, using geophysical logs and oil yields from Fischer assay, that key oil-shale zones could be traced between the Uinta and Piceance Basins across the intervening Douglas Creek arch area. The Mahogany oil-shale

bed of the Parachute Creek Member of the Green River Formation is the most widespread marker bed in the Green River Formation. It was deposited during the most expansive stage of Eocene Lake Uinta (Johnson, 1985) and occurs throughout much of the Uinta and Piceance Basins.

Structure Contour Maps and Isopach Maps

Four structure contour maps and three isopach maps were constructed using data in table 1 and are included in this report. Structure contour maps in ascending stratigraphic order are: top of the lower tongue of the Castlegate Sandstone (fig. 3); top of the Mesaverde Group (fig. 4); base of the Long Point Bed (fig. 5); and top of the Mahogany oil-shale bed (fig. 6). Isopach maps in ascending stratigraphic order are: top of the lower tongue of the Castlegate Sandstone to top of the Mesaverde Group (fig. 7); top of the Mesaverde Group to base of the Long Point bed (fig. 8); and base of the Long Point Bed to top of the Mahogany oil-shale bed (fig. 9). The boundaries of the Uinta-Piceance Province, Mesaverde Total Petroleum System, and Green River Total Petroleum System are from the Uinta-Piceance oil and gas assessment. The maps were generated using Earth Vision (Dynamic Graphics, Inc., 1999, v. 5)—a two-dimensional surface-modeling program.

The oldest isopach interval, from the top of the lower tongue of the Castlegate Sandstone to the top of the Mesaverde Group (fig. 7), shows little evidence for differential subsidence between the basin margin and the basin trough during this time period. First evidence for the development of the Uinta Basin occurs in the isopach map from the top of the Mesaverde Group to the base of the Long Point Bed (fig. 8). This interval thickens from less than 500 ft along the west flank of the Douglas Creek arch to more than 6,000 ft near the basin trough. Johnson and Finn (1986, fig. 9) previously documented the thickening of this interval toward the trough of the basin for a more restricted area of the basin. The youngest isopach interval, from the base of the Long Point Bed to the top of the Mahogany oil-shale bed (fig. 9), displays a similar trend, thickening from less than 1,500 ft along the west flank of the Douglas Creek arch to more than 3,000 ft near the basin trough. This interval also thins to less than 2,250 ft toward the north margin of the basin. Johnson and Finn (1986, fig. 12) also published an isopach map of this interval that displayed a similar thickening trend toward the basin trough and a slight thinning of this interval toward the north margin of the basin.

Thinning of the interval from the top of the lower tongue of the Castlegate Sandstone to the top of the Mesaverde Group toward the San Rafael Swell (fig. 7) is probably caused by differential erosion of this interval beneath the unconformity at the top of the Mesaverde Group. Differential erosion of Upper Cretaceous strata beneath the Cretaceous-Tertiary unconformity

toward the swell was previously documented by Lawton (1986, fig. 11). However, the two younger isopach intervals, from the top of the Mesaverde Group to the base of the Long Point Bed (fig. 8) and from the base of the Long Point Bed to the top of the Mahogany bed (fig. 9), show no evidence of thinning toward the San Rafael Swell and instead show a thickening toward the northwest in the vicinity of the swell. The San Rafael Swell was again active in post-Mahogany time. The structure contour map on the youngest unit contoured, the top of the Mahogany oil-shale bed (fig. 6), indicates significant post-Mahogany uplift on the San Rafael Swell. These maps suggest that movement on the San Rafael Swell was not continuous throughout Late Cretaceous through Eocene time, and may have largely been confined to very early and very late in this time period.
